Experiment No. 4

Analyzing Power Query M Code to Differentiate Transformations

Student Name: Sufiyan Surve

Roll Number: 60

Domain: EV Charging

Observation 1

Power Query M code records data-cleaning and transformation operations as sequential steps. The `let` statement defines the source and transformation steps, while the `in` statement returns the final result of the query.

Observation 2

Append combines rows from multiple tables with compatible columns, such as monthly EV charging records. Merge joins tables using matching column values, such as Station_Name, to add related station details to charging-session records.

Note: Confirm that these observations match the actual Applied Steps and M code in your Power Query project.
